Magnetic-field symmetry of pump currents of adiabatically driven mesoscopic structures

MOSKALETZ, Mykhaylo, BUTTIKER, Markus

Abstract

We examine the scattering properties of a slowly and periodically driven mesoscopic sample using the Floquet function approach. One might expect that at sufficiently low driving frequencies it is only the frozen scattering matrix which is important. The frozen scattering matrix reflects the properties of the sample at a given instant of time. Indeed many aspects of adiabatic scattering can be described in terms of the frozen scattering matrix. However, we demonstrate that the Floquet scattering matrix, to first order in the driving frequency, is determined by an additional matrix which reflects the fact that the scatterer is time dependent. This low-frequency irreducible part of the Floquet matrix has symmetry properties with respect to time and/or a magnetic field direction reversal opposite to that of the frozen scattering matrix. Using the adiabatic decomposition of the Floquet scattering matrix we split the dc current flowing through the pump into several parts with well defined properties with respect to a magnetic field inversion.

(Dated: February 2, 2008)

We examine the scattering properties of a slowly and periodically driven mesoscopic sample using the Floquet function approach. One might expect that at sufficiently low driving frequencies it is only the frozen scattering matrix which is important. The frozen scattering matrix reflects the properties of the sample at a given instant of time. Indeed many aspects of adiabatic scattering can be described in terms of the frozen scattering matrix. However, we demonstrate that the Floquet scattering matrix, to first order in the driving frequency, is determined by an additional matrix which reflects the fact that the scatterer is time-dependent. This low frequency irreducible part of the Floquet matrix has symmetry properties with respect to time and/or a magnetic field direction reversal opposite to that of the frozen scattering matrix. We investigate the quantum rectification properties of a pump which additionally is subject to an external dc voltage. We split the dc current flowing through the pump into several parts with well defined properties with respect to a magnetic field and/or an applied voltage inversion.

I. INTRODUCTION

The interplay of quantum mechanical interference with quantized energy exchange results in a quantum pump effect which is investigated intensively both experimentally and theoretically. This phenomenon being promising for manipulating and controlling the passage of electrons through mesoscopic circuits is of fundamental interest. Adiabatic driving involves only low energy exchange and avoids excitations into inelastic channels which degrade the quantum properties of the system. In this work we investigate the magnetic symmetry properties of the dc-current of a quantum pump which might operate in the presence of applied voltages and temperature gradients.

The experimentally measured adiabatically pumped dc current\textsuperscript{1} flowing through a chaotic cavity with periodically varying shape is symmetric in magnetic field $H$. That is in seeming contradiction with the theory\textsuperscript{8,10,12,14,16} predicting that the pumped current has no definite symmetry under magnetic field reversal. As a result it was conjectured\textsuperscript{37,40} that the current measured in Ref.\textsuperscript{8} is caused by a classical rectification effect. Indeed subsequent measurements\textsuperscript{8} confirmed that for slow one-parameter driving there is a symmetric in magnetic field induced current whose origin is classical rectification. Nevertheless one can not exclude the possibility that the current measured in Ref.\textsuperscript{8} contains also the contribution coming from the quantum pump effect. To check it, perhaps, it is necessary to investigate the system in a less symmetric setup, i.e., with reservoirs having different electrochemical potentials or temperatures. In the present paper we give a simple example when the pumped current has or has not an odd in magnetic field contribution depending on whether there is or there is no applied voltage. Further experimental and theoretical efforts to detect and distinguish the quantum pump effect are highly desirable in view of a possible application in quantum information processing devices\textsuperscript{40,41}.

The aim of the present paper is to explore in detail the symmetry properties of the adiabatic current generated by the periodically driven mesoscopic conductor. To this end we represent the Floquet scattering matrix at low driving frequency $\omega$ as a sum of different terms with well defined symmetry properties (e.g., with respect to a magnetic field direction reversal). One term reflects the symmetry of a stationary scattering process while the other term vanishing at $\omega \rightarrow 0$ has symmetry properties opposite to a stationary scattering process. Based on such a representation we divide the dc current into parts with well defined symmetry properties. That opens up additional possibilities for the experimental detection of the quantum pump effect.

In particular, in the two terminal case, we find a voltage dependent contribution to the pumped current which is odd in magnetic field. At small voltage this current is linear in $V$. Thus for small magnetic fields the dc-current has a component which is proportional to the product of frequency, magnetic field, and applied voltage. For comparison we recall that in the stationary case, for a two-terminal conductor, the current linear in voltage (or, alternatively, the conductance) is an even function of a magnetic field\textsuperscript{42,43} and is caused by electron-electron interactions. In contrast, in the non-stationary case considered here even non-interacting electrons can show a response that is odd in magnetic field and linear in applied voltage.

Recently the magnetic field symmetry of the dc current through an open quantum dot subject to a one-parameter potential oscillation has been investigated experimentally and theoretically as a function of frequency\textsuperscript{8} In contrast, in the present paper we consider a two-parameter oscillation and...
investigate the magnetic field symmetry of the dc current in the presence of adiabatic parametric quantum pumping. The paper is organized as follows. In Sec. III we briefly consider the Floquet function approach to scattering of electrons at a periodically driven mesoscopic conductor and analyze the consequences of microscopic reversibility. We introduce an exact representation for the scattering matrix at low driving frequency $\omega$. According to this representation the Floquet scattering matrix elements (up to linear in $\omega$ terms) are proportional to the elements of both the stationary scattering matrix $S_0$ and a residual Floquet matrix $\hat{A}$ which exhibits symmetry properties opposite to those of $S_0$. The symmetry properties of $S_0$ are dictated by micro-reversibility, and the residual Floquet matrix $\hat{A}$ reflects directly the breaking of these symmetries due to the driving of the sample. Using such a representation we analyze the magnetic field symmetry of the dc current flowing through the adiabatically driven scatterer in Sec. III. We show that in the two terminal case there is a dc current $I^{(\text{od})}$ that is odd in magnetic field, linear in $\omega$ and dependent on the applied voltage. To calculate correctly $I^{(\text{od})}$ it is necessary to find the residual Floquet matrix $\hat{A}$. Using several simple examples we outline the method for calculating $\hat{A}$ in Sec. IV. We conclude in Sec. V.

II. GENERAL APPROACH

We use the scattering matrix approach\textsuperscript{54,55,56,57,58,59,60,61} which views the mesoscopic sample as a scatterer which causes transmission and reflection of incident carriers. The scatterer is assumed to be coupled to $N_r$ reservoirs via single channel ballistic leads which we will number by the Greek letters $\alpha, \beta$, etc.

We assume that in the stationary case electrons coming from the reservoirs and interacting with the scatterer are subject only to elastic scattering. Such (single particle) scattering can be described with the help of the scattering matrix $S_0$. The index 0 denotes the stationary scattering matrix. In general $S_0$ is a function of the electron energy $E$. This matrix collects all the quantum mechanical amplitudes for electrons coming from some lead $\beta$ to be scattered into the same or any other lead $\alpha$. These amplitudes are normalized in such a way that their square define the corresponding particle fluxes (currents). If the electron velocities at a given energy are the same in all the leads we can use these amplitudes to relate the incident and out-going wave functions. For instance, let $\Psi^{(\text{in})}_{\alpha,0}(E,t) = e^{-i\frac{E}{\hbar}t}\psi^{(\text{in})}_{\alpha,0}(E)$, be the amplitude of a wave function describing electrons with energy $E$ incident in lead $\alpha$. Then the amplitude of the wave function of particles outgoing in lead $\alpha$, $\Psi^{(\text{out})}_{\alpha,0}(E,t) = e^{-i\frac{E}{\hbar}t}\psi^{(\text{out})}_{\alpha,0}(E)$, is defined as follows:

$$\psi^{(\text{out})}_{\alpha,0}(E) = \sum_{\beta=1}^{N_r} S_{\alpha,\beta}(E)\psi^{(\text{in})}_{0,\beta}(E).$$  (1)

Current conservation implies that the scattering matrix is a unitary matrix:\textsuperscript{55,56,57,58,59,60,61}

$$\hat{S}_0^\dagger \hat{S}_0 = \hat{S}_0 \hat{S}_0^\dagger = \hat{I},$$  (2)

where $\hat{I}$ is a unit matrix. In fact, the knowledge of the matrix $\hat{S}_0(E)$ is equivalent to the knowledge of the solution for the stationary Schrödinger equation.

For the dynamical problem with time-dependent scattering, scattering is characterized by the integral scattering operator which depends on two times.\textsuperscript{60} One-time-argument relates to the incoming states and the second time-argument to the outgoing states. In this paper we are dealing with a particular non stationary case, namely with a periodically driven scattering problem. We assume that the scattering potential (hence the scattering properties of a sample) is varied in time periodically with period $T = 2\pi/\omega$. Then, according to the Floquet theorem (see, e.g., Refs. 48-52, the solution for the time-dependent Schrödinger equation can be represented in a relatively simple form

$$\Psi(E,t) = e^{-i\frac{E}{\hbar}t} \sum_{n=-\infty}^{\infty} e^{-in\omega t} \psi(E_n).$$  (3)

Here $E$ is the Floquet energy; $\psi(E_n)$ is a general solution of the stationary Schrödinger equation corresponding to the energy $E_n = E + n\hbar\omega$.

Scattering on such an oscillatory scatterer can be described via the Floquet scattering matrix. In this work we are concerned with the low-frequency properties of this dynamical problem and the relevant Floquet matrix $\hat{S}_F$ describes the transitions between the propagating states only.\textsuperscript{58} The elements $S_{\gamma,\alpha,\beta}(E_n,E)$ of this matrix are the quantum mechanical amplitudes (normalized for current) for an electron with energy $E$ to enter the scatterer through lead $\beta$ and to leave the scatterer with energy $E_n = E + n\hbar\omega$. The solution of the Floquet scattering problem with time dependent scattering can be represented in the form

$$\psi^{(\text{out})}_{\alpha}(E_n) = \sum_{\beta=1}^{N_r} \sum_{m} \frac{F_{E_n}}{k_n} S_{\alpha,0,\beta}(E_n,E_m) \psi^{(\text{in})}_{0,\beta}(E_m).$$  (4)

Here $k_n = \sqrt{2m_e E_n}/\hbar$ with $m_e$ being the electron mass. Physically Eq. (4) means that an electron interacting with an oscillating scatterer can gain or lose one or several energy quanta $n\hbar\omega$, $n = 0, \pm 1, \pm 2, \ldots$, and thus an electron can change its energy by a discrete amount $n\hbar\omega$.

Current conservation implies again that the matrix $\hat{S}_F$ is unitary. For the Floquet scattering matrix the analog of Eq. (2) reads as follows:

$$\sum_{\alpha} S_{\alpha,0,\beta}^* S_{\alpha,\gamma}(E_n,E) S_{\alpha,\gamma}(E_n,E_m) = \delta_{\alpha 0}\delta_{\beta \gamma},$$  (5a)

$$\sum_{\beta} S_{\alpha,0,\beta}^* S_{\alpha,\gamma}(E_n,E) S_{\alpha,\gamma}(E_n,E_m) = \delta_{\alpha 0}\delta_{\beta \gamma}. $$  (5b)

Here the summation over $n$ goes only over those $n$ which correspond to a positive $E_n = E + n\hbar\omega$. In the low frequency limit we have $\hbar\omega \ll E$, and thus $n$ extends from $-\infty$ to $+\infty$.

To find the Floquet scattering matrix one needs to solve a fully time-dependent Schrödinger equation. Compared to the stationary problem, this is a more difficult and, generally, it can be done only numerically. On the other hand the representation Eq. (3) seems effectively to reduce the periodically driven case to the stationary one. Therefore it is attractive to try to relate the Floquet scattering matrix $\hat{S}_F$ to the stationary scattering matrix $\hat{S}_0$. 

A. Adiabatic approximation

Let the stationary scattering matrix $\hat{S}_0(E, \{ p \})$ depend on a set of parameters $p_i \in \{ p \}, i = 1, 2, \ldots, N_p$ (e.g., the sample’s shape, the strength of coupling to leads, the magnetic field, etc.). Varying these parameters one can change the scattering properties of a sample. We take these parameters to be periodic functions in time: $p_i(t) = p_i(t + T), \forall i$. Then the matrix $\hat{S}_0$ becomes time-dependent: $\hat{S}_0(E, t) = \hat{S}_0(E, \{ p(t) \})$. In general the matrix $\hat{S}_0(t)$ does not describe the scattering of electrons by a time-dependent scatterer: only the Floquet scattering matrix $\hat{S}_F$ does. Nevertheless in the low frequency limit, $\omega \rightarrow 0$, there exists a connection between these two matrices. This connection becomes more evident if one represents the Floquet scattering matrix elements as a series in powers of $\omega$.

1. zeroth order approximation

To zero-th order in the driving frequency the elements of the Floquet scattering matrix $\hat{S}_F(E, n)$ can be approximated by the Fourier coefficients $\hat{S}_{0,n}$ of the stationary scattering matrix $\hat{S}_0$ as follows:

$$\hat{S}_F(E, n) = \hat{S}_{0,n}(E) + O(\omega). \quad (6a)$$

Here $O(\omega)$ denotes the rest which is at least first order in frequency $\omega$ and which is neglected in the zero-th order adiabatic approximation. The Fourier transformation used reads as follows:

$$\hat{S}_0(E, t) = \sum_{n=\infty} e^{-in\omega t} \hat{S}_{0,n}(E), \quad (7a)$$

$$\hat{S}_{0,n}(E) = \frac{1}{T} \int_0^T e^{-in\omega t} \hat{S}_0(E, t). \quad (7b)$$

Before proceeding we check that this approximation is consistent with the current conservation condition. Substituting $\hat{S}_F$ into Eq. (5) and performing the inverse Fourier transformation we arrive at Eq. (6).

Equation (7) corresponds to the frozen scattering matrix approximation. Within this approximation the stationary scattering matrix (with parameters dependent on time) completely characterizes the time-dependent scattering. This approximation is exact if the scattering matrix $\hat{S}_0$ is independent of the electron energy $E$ within the relevant energy interval.

2. first order approximation

To first order in the pump-frequency $\omega$ we can represent the Floquet matrix with the help of the frozen scattering matrix, its energy derivatives and a matrix $\hat{A}$. In general the matrix $\hat{A}$ can not be expressed in terms of the stationary scattering matrix $\hat{S}_0$ and it has to be calculated (like $\hat{S}_0$ itself) in each particular case. The advantage of the representation which we introduce is that the matrix $\hat{A}$ has a much smaller number of elements than the Floquet scattering matrix. The matrix $\hat{A}$ depends on only one energy, $E$, and therefore it has $N_r \times N_r$ elements like the stationary scattering matrix $\hat{S}_0$. In contrast, the Floquet scattering matrix $\hat{S}_F$ depends on two energies, $E$ and $E_n = E + n\hbar \omega$, and therefore has $\sim (2n_{\text{max}} + 1) \times N_r \times N_r$ relevant elements. Here $n_{\text{max}}$ is the maximum number of energy quanta $\hbar \omega$ absorbed/emitted by an electron interacting with the scatterer which we should take into account to correctly describe the scattering process. For small amplitude driving we have $n_{\text{max}} \approx 1$. In contrast, if the parameters vary with a large amplitude then $n_{\text{max}} \gg 1$. We represent the Floquet matrix in the form:

$$\hat{S}_F(E, n) = \hat{S}_{0,n}(E) + \frac{n\hbar \omega}{2} \frac{\partial \hat{S}_{0,n}(E)}{\partial E} + \hbar \omega \hat{A}_n(E) + O(\omega^2), \quad (8a)$$

$$\hat{S}_F(E, E_n) = \hat{S}_{0,n}(E) + \frac{n\hbar \omega}{2} \frac{\partial \hat{S}_{0,n}(E)}{\partial E} + \hbar \omega \hat{A}_{-n}(E) + O(\omega^2). \quad (8b)$$

Note the right hand side (RHS) of Eq. (8) is defined with respect to the incoming energy of carriers, while in Eq. (5) the RHS is expressed in terms of the energy of outgoing particles. To first order in $\omega$, the case of interest here, these two representations are fully consistent. Going from one representation to the other, one needs to take into account that the contribution from the first term on the RHS depends on the choice of the reference energy. The second and the third terms being themselves proportional to $\omega$ do not depend on this choice.

In Eq. (8) we have introduced a new matrix $\hat{A}(E, t)$ with Fourier coefficients $\hat{A}_n(E)$. The current conservation condition, Eq. (4), leads to the following equation for the matrix $\hat{A}(E, t)$:

$$\hbar \omega \left( \hat{S}_{0,n}^\dagger(E, t) \hat{A}(E, t) + \hat{A}^\dagger(E, t) \hat{S}_0(E, t) \right) = \frac{1}{2} \mathcal{P} \{ \hat{S}_{0,n}^\dagger, \hat{S}_0 \}. \quad (9a)$$

$$\mathcal{P} \{ \hat{S}_{0,n}^\dagger, \hat{S}_0 \} = i\hbar \left( \frac{\partial \hat{S}_{0,n}^\dagger}{\partial t} \frac{\partial \hat{S}_0}{\partial E} - \frac{\partial \hat{S}_{0,n}^\dagger}{\partial E} \frac{\partial \hat{S}_0}{\partial t} \right). \quad (9b)$$

Note the matrix $\mathcal{P} \{ \hat{S}_{0,n}^\dagger, \hat{S}_0 \}$ is traceless. Another but equivalent representation can be obtained from Eq. (9) multiplying both sides from the left by $\hat{S}_0$ and from the right by $\hat{S}_{0,n}^\dagger$ and by taking into account that because of the unitarity condition, Eq. (2), we have $\delta \omega [\hat{S}_{0,n}^\dagger, \hat{S}_0] = -i [\hat{S}_{0,n}^\dagger, \hat{S}_0]$.

We remark that Eq. (9) tells us that the expansion in powers of $\omega$ is, in fact, an expansion in powers of $\hbar \omega/\delta E$, where $\delta E$ is the energy scale over which the scattering matrix $\hat{S}_0(E)$ changes significantly. Therefore, the frequency $\omega$ can be considered as slow and the expansion Eq. (9) can be relevant if

$$\hbar \omega \ll \delta E. \quad (10)$$

Consequently, to characterize scattering with an accuracy of order $\omega$ one needs to determine the matrix $\hat{A}$. Equation (10) defines only the anti commutator of two matrices, $\hat{S}_0$ and $\hat{A}$, and it is insufficient to determine the matrix $\hat{A}$.

By analogy with Eq. (6) we can express the Floquet scattering matrix elements up to first order in driving frequency in terms of the Fourier coefficients of some effective matrix. We introduce two matrices $\hat{S}_{in}$ and $\hat{S}_{out}$ defined with respect to incoming and outgoing energies, respectively:

$$\hat{S}_{in}(E, t) = \hat{S}_0(E, t) + i\hbar \frac{\partial^2 \hat{S}_0}{\partial t^2} + \hbar \omega \hat{A}(E, t). \quad (11a)$$
\[ \hat{S}_{\text{out}}(E,t) = \hat{S}_0(E,t) - \frac{i\hbar}{2} \frac{\partial^2 \hat{S}_0}{\partial E^2} + \hbar \omega \hat{A}(E,t). \]  

(11b)

Performing the Fourier transformation of Eqs. (11) and comparing the result with Eqs. (8), we find:

\[ \hat{S}_F(E_n, E) = \hat{S}_{\text{in},n}(E) + O(\omega^2). \]  

(12a)

\[ \hat{S}_F(E, E_n) = \hat{S}_{\text{out},-n}(E) + O(\omega^2). \]  

(12b)

We emphasize that the matrices \( \hat{S}_{\text{in}}(t) \) and \( \hat{S}_{\text{out}}(t) \) are not scattering matrices because they are not unitary: Their Fourier coefficients just define the corresponding matrix elements of the Floquet scattering matrix according to Eq. (12). Nevertheless, these matrices conserve the current "on average", i.e., after integrating over the time period T:

\[ \int_0^T \hat{S}_{\text{in}}^\dagger(E,t) \hat{S}_{\text{in}}(E,t) = \hat{I} + O(\omega^2). \]  

(13a)

\[ \int_0^T \hat{S}_{\text{out}}^\dagger(E,t) \hat{S}_{\text{out}}(E,t) = \hat{I} + O(\omega^2). \]  

(13b)

Now we use Eq. (9) to analyze the general properties of the matrix \( \hat{A} \) which are due to the micro reversibility of the Schrödinger equation with a periodically oscillating potential.

\[ \hat{F}(E) = \hat{S}_0(E) \hat{H}(E) \hat{S}_0^\dagger(E), \]  

where the upper index "T" denotes transposition.

Next we consider a periodically driven scattering problem. As we saw micro-reversibility requires the scattering matrix to be symmetric with respect to the interchange of incoming and outgoing channels. For the Floquet scattering matrix these channels are characterized by both the lead index and the number \( n \) showing how many energy quanta \( \hbar \omega \) an electron absorbs/emits during the scattering process. In addition, to get the required symmetry condition, we have to take into account that the parameters \( p_i \) of the Hamiltonian depend on time.

B. Micro-reversibility and magnetic field symmetry of the Floquet scattering matrix

We start with the stationary case when the single particle Hamiltonian (and correspondingly the scattering matrix) is independent of time and recall some properties of the stationary scattering matrix, such as

The micro-reversibility of the equation of motion (i.e., the Schrödinger equation) puts some constraints onto the scattering matrix. To make the notation more convenient let us arrange the incoming/outgoing wave functions at all the leads into the vector column

\[ \hat{\psi} = \begin{pmatrix} \psi_1 \\ \psi_2 \\ \vdots \\ \psi_N \end{pmatrix}. \]  

(14)

Then Eq. (1) can be written in the compact form:

\[ \hat{\psi}^{(\text{out})} = \hat{S}_0 \hat{\psi}^{(\text{in})}. \]  

(15)

The micro-reversibility condition (i.e., the invariance with respect to the time inversion) for the spin less case under consideration leaves the solution of the scattering problem invariant under the simultaneous inversion of the direction of movement, the inversion of a possibly present magnetic field \( H \), and the replacement \( \Psi \rightarrow \Psi^* \). Therefore, the evolution of the two wave functions, namely \( \Psi(E,H,t) \) and \( \Psi^*(E,-H,-t) \), is exactly the same and is described by the same scattering matrix \( \hat{S}_0 \). Taking into account that the inversion of the direction of movement turns the outgoing waves to incoming ones and vice versa we can write the following equations for the starting solution and its transform:

\[ \hat{\psi}^{(\text{out})}(E, H) = \hat{S}_0(E, H) \hat{\psi}^{(\text{in})}(E, H), \]  

(16a)

\[ \left( \hat{\psi}^{(\text{in})}(E, -H) \right)^* = \hat{S}_0(E, H) \left( \hat{\psi}^{(\text{out})}(E, -H) \right)^*. \]  

(16b)

From the unitarity condition Eq. (2) it follows that \( \hat{S}_0^{-1} = \hat{S}_0^\dagger \). Therefore we can rewrite Eq. (16a) as follows: \( \hat{\psi}^{(\text{in})}(E, H) = \hat{S}_0^\dagger(E, H) \hat{\psi}^{(\text{out})}(E, H) \). Comparing this with Eq. (16b) we arrive at the required condition

\[ \hat{S}_0(-H) = \hat{S}_0^\dagger(H), \]  

(17)

where the upper index "T" denotes transposition.

Next we consider a periodically driven scattering problem. As we saw micro-reversibility requires the scattering matrix to be symmetric with respect to the interchange of incoming and outgoing channels. For the Floquet scattering matrix these channels are characterized by both the lead index and the number \( n \) showing how many energy quanta \( \hbar \omega \) an electron absorbs/emits during the scattering process. In addition, to get the required symmetry condition, we have to take into account that the parameters \( p_i \) of the Hamiltonian depend on time. We suppose they change periodically in time with the same frequency \( \omega \) and with possible relative phase shifts \( \varphi_i \).

\[ p_i(t) = p_{i,0} + p_{i,1} \cos(\omega t + \varphi_i). \]  

(18)

In such a case time reversal implies the inversion of the sign of all the phase shifts \( \varphi_i \). Therefore, the Floquet scattering matrix elements are subject to the following fundamental symmetry:

\[ S_{F,\alpha\beta}(E, E_n; H, \varphi) = S_{F,\beta\alpha}(E_n, E; -H, -\varphi), \]  

(19a)

or in a matrix form

\[ \hat{S}_F(E; -H, -\varphi) = \hat{S}_F^\dagger(E; H, \varphi). \]  

(19b)

Here \( E \) is the Floquet energy [see, Eq. (2)]; \( \varphi \) denotes the set of all the \( \varphi_i \).

Next we derive the symmetry conditions for the matrix \( \hat{A} \) entering Eq. (3). Our definition of the phases \( \varphi \) [see, Eq. (13)] implies that the frozen scattering matrix \( \hat{S}_0(E,t) \) [i.e., the stationary scattering matrix with parameters dependent on time \( \hat{S}_0(E,t) = \hat{S}_0(E,p_i(t)) \) ] possesses the following symmetry

\[ \hat{S}_0(E, -t; H, -\varphi) = \hat{S}_0(E, t; H, \varphi). \]  

(20)

Then equation (10) gives us:

\[ \hat{A}(E, -t; H, -\varphi) = -\hat{A}(E, t; H, \varphi). \]  

(21)

Correspondingly, for the Fourier coefficients, we have the following:

\[ \hat{S}_{0,n}(E; H, -\varphi) = \hat{S}_{0,-n}(E; H, \varphi), \]  

(22a)

\[ \hat{A}_n(E; H, -\varphi) = -\hat{A}_{-n}(E; H, \varphi). \]  

(22b)

Substituting the equations given above into the adiabatic expansion, Eqs. (3), and taking into account the micro reversibility condition, Eq. (19b), we find the required symmetry condition for the matrix \( \hat{A}(t) \):

\[ \hat{A}(-H) = -\hat{A}^T(H). \]  

(23)
In particular, in the absence of magnetic fields, $H = 0$, the diagonal elements of $A$ vanish. That was previously shown in Ref. [33]. Alternatively equation (23) can be obtained directly from Eq. (9) exploiting the symmetry condition Eq. (11) and the unitarity of the frozen scattering matrix $\hat{S}_0(E,t)$.

The symmetry properties of the residual Floquet matrix $\hat{A}$ are completely different from that of the stationary scattering matrix $\hat{S}_0$. The residual Floquet matrix $\hat{A}$ reflects directly the most important differences between an adiabatic scattering process versus a periodically evolving scattering and a strictly stationary scattering process.

III. MAGNETIC FIELD SYMMETRY OF THE DC CURRENT FLOWING THROUGH THE SLOWLY DRIVEN SCATTERER

Now we use the results of the previous section to analyze the dc current through the mesoscopic sample with periodically varying parameters. We will consider two mechanisms which can give rise to such a current. The first mechanism is a quantum pump effect consisting in rectifying of time-dependent currents generated by the non stationary scattering matrix $\hat{A}$. Second we permit a constant in time difference of electrochemical potentials/temperatures between the different reservoirs. The last is important, because the widely investigated situation with reservoirs being at the same electrochemical potentials/temperatures between the different reservoirs. However in the two terminal case the odd in magnetic field contributions to both the even and the odd, $I^{(e)}\alpha(\alpha) = I^{(o)}\alpha(\alpha)$, respectively, of the pump scattering processes.

The dc current $I_\alpha$ flowing from the scatterer to the reservoir in the lead $\alpha$ can be calculated as follows:

$$ I_\alpha = e \int_0^\infty dE \left\{ \sum_{\beta=1}^{N_r} \sum_{n} |S_{F,\alpha\beta}(E,E)|^2 f_{0,\beta}(E) - f_{0,\alpha}(E) \right\}. $$

(24)

Here $f_{0,\alpha}(E)$ is the electron distribution function for the reservoir $\alpha$. We assume that the reservoirs are in a stationary equilibrium state with possibly different electrochemical potentials $\mu_\alpha$ and temperatures $T_\alpha$. Then $f_{0,\alpha}$ is the Fermi distribution function

$$ f_{0,\alpha}(E) = \frac{1}{1 + e^{(E - \mu_\alpha)/k_B T_\alpha}}, $$

(25)

with $k_B$ being the Boltzmann constant. Substituting the adiabatic expansion Eq. (8) into Eq. (24) and performing the inverse Fourier transformation we find the current up to linear in $\omega$ terms as follows:

$$ I_\alpha = \int_0^\infty dE \int_0^\infty dt \sum_{\beta} \left\{ f_{0,\beta}(E) \frac{dI_{\alpha\beta}(E,t)}{dE} \right\} + \frac{e}{\hbar} \left( \sum_{\beta} |S_{0,\alpha\beta}(E,t)|^2 \right) [f_{0,\beta}(E) - f_{0,\alpha}(E)] \right\}, $$

(26)

where $dI_{\alpha\beta}/dE$ is a spectral current driven by the non stationary scattering from lead $\beta$ into lead $\alpha$:

$$ \frac{dI_{\alpha\beta}}{dE} = \frac{e}{\hbar} \left( \hbar \omega \Re [S_{0,\alpha\beta} A_{\beta\alpha}] + \frac{1}{2} \mathcal{P} \{ S_{0,\alpha\beta}; S_{0,\alpha\beta}^* \} \right). $$

(27)

Here $\Re[X]$ is the real part of $X$; the function $\mathcal{P}\{X; Y\}$ is defined in Eq. (21). The spectral currents $dI_{\alpha\beta}/dE$ are subject to the following conservation law:

$$ \sum_{\alpha=0}^{N_r} \int \frac{dI_{\alpha\beta}(E,t)}{dE} = 0, $$

(28)

Using Eq. (28) and the unitarity of the frozen scattering matrix, $\sum_{\alpha} |S_{0,\alpha\beta}|^2 = \sum_{\beta} |S_{0,\alpha\beta}|^2 = 1$, one can easily check that the current $I_\alpha$ is conserved: $\sum_{\alpha} I_\alpha = 0$. Further, using the symmetry conditions, Eqs. (17) and (23), and rearranging the terms in Eq. (26) we divide the current into the even, $I^{(e)}_\alpha(\alpha) = I^{(e)}_\alpha(-\alpha)$, and odd, $I^{(o)}_\alpha(\alpha) = -I^{(o)}_\alpha(-\alpha)$, in magnetic field parts:

$$ I^{(e)}_\alpha(\alpha) = \frac{e}{\hbar} \int_0^\infty dE \int_0^\infty dt \sum_{\beta} \left\{ f_{0,\beta}(E) - f_{0,\alpha}(E) \right\} \times \left( |S_{0,\alpha\beta}|^2 + |S_{0,\alpha\beta}|^2 \right) \left\{ \hbar \omega \Re [S_{0,\alpha\beta} A_{\beta\alpha}] - S_{0,\alpha\beta} S_{0,\alpha\beta}^* A_{\beta\alpha} \right\}, $$

(29a)

$$ I^{(o)}_\alpha(\alpha) = \frac{e}{\hbar} \int_0^\infty dE \int_0^\infty dt \sum_{\beta} \left\{ f_{0,\beta}(E) - f_{0,\alpha}(E) \right\} \times \left( |S_{0,\alpha\beta}|^2 + |S_{0,\alpha\beta}|^2 \right) \left\{ \hbar \omega \Re [S_{0,\alpha\beta} A_{\beta\alpha}] + S_{0,\alpha\beta} S_{0,\alpha\beta}^* A_{\beta\alpha} \right\}. $$

(29b)

To show that both these currents are separately conserved, i.e., that $\sum_{\alpha} I^{(e)}_\alpha = 0$ and $\sum_{\alpha} I^{(o)}_\alpha = 0$, one can use the relations

$$ 4\hbar \omega \sum_{\alpha=1}^{N_r} \Re [S_{0,\alpha\beta} A_{\beta\alpha}] = \mathcal{P} \{ S_{0,\beta\alpha}; S_{0,\beta\alpha}^* \}, $$

(30a)

$$ 4\hbar \omega \sum_{\beta=1}^{N_r} \Re [S_{0,\alpha\beta} A_{\beta\alpha}] = \mathcal{P} \{ S_{0,\alpha\beta}; S_{0,\alpha\beta}^* \}, $$

(30b)

which follow from Eq. (14).

In a general multi-terminal situation, i.e., if not all the reservoirs are at the same potential (temperature), the main contributions to both the even $I^{(e)}_\alpha(\alpha)$ and the odd $I^{(o)}_\alpha(\alpha)$ currents are proportional to the conductances $\frac{1}{\hbar^2} |S_{0,\alpha\beta}|^2$ averaged over time. The non-stationarity only makes the small corrections. However in the two terminal case the odd in magnetic field dc current $I^{(o)}_\alpha(\alpha)$ has no contribution coming from the conductances. The current $I^{(o)}_\alpha(\alpha)$ is linear in $\omega$ and it is entirely due to the non-adiabaticity of the pump scattering processes.

A. Two terminal many channel scatterer

To show this let us consider the scatterer connected to only two reservoirs via, possibly many channel, ballistic leads. We will mark the quantities related to the left and to the right reservoirs via the lower indices "L" and "R", respectively. Let the lead have $N_L$ channels, and the right lead have $N_R$ channels: $N_L + N_R = N_r$. We define the currents flowing to the left $I_L$ and to the right $I_R = -I_L$, and the distribution functions for the left $f_{0,L}$ and for the right $f_{0,R}$ reservoirs as follows:

$$ I_L = \sum_{\alpha=1}^{N_L} I_\alpha, \quad f_{0,\alpha} = f_{0,L}, \quad 1 \leq \alpha \leq N_L, $$

$$ I_R = \sum_{\alpha=N_L+1}^{N_r} I_\alpha, \quad f_{0,\alpha} = f_{0,R}, \quad N_L + 1 \leq \alpha \leq N_r. $$

(29a)
By analogy we redefine the quantities dependent on two indices. For example, the reflection to the left $R_{LL}$ and the spectral current $dI_{RL}/dE$ driven from the left to the right are defined as follows:

$$R_{LL} = \sum_{\alpha=1}^{N_L} \sum_{\beta=1}^{N_L} |S_{\alpha,\beta}|^2,$$

$$\frac{dI_{RL}}{dE} = \sum_{\alpha=1}^{N_L} \sum_{\beta=1}^{N_L} \frac{dI_{RL}}{dE} \alpha \beta.$$

Note that the two terminal transmission is symmetric in reservoir indices, $T_{RL} = T_{LR}$, and it is even in magnetic field. That can be easily seen from their definition, similar to the one given above for $R_{LL}$, and from the unitarity of the scattering matrix $\hat{S}_0$, Eq. (2). In addition from Eq. (28) we get:

$$dL_{LL}/dE + dL_{RR}/dE = 0,$$

performing necessary summations in Eqs. (30), and integrating by parts over time and over energy, we get:

$$I_{L}^{(ev)} = \frac{e}{h} \int_0^\infty dE \int_0^\infty dt \left\{ f_0, R - f_{0, L} \right\}$$

$$\times \left( T_{LR} + \sum_{\alpha=1}^{N_L} \sum_{\beta=1}^{N_L} \left( \frac{\partial S_0}{\partial t} \frac{\partial S_0}{\partial t} - \frac{\partial S_0}{\partial t} \frac{\partial S_0}{\partial t} \right) \alpha \beta \right\},$$

$$I_{L}^{(od, ev)} = \frac{e}{h} \int_0^\infty dE \int_0^\infty dt \left\{ f_0, R + f_{0, L} \right\},$$

$$\times \left( T_{LR} + \sum_{\alpha=1}^{N_L} \sum_{\beta=1}^{N_L} \left( \frac{\partial S_0}{\partial t} \frac{\partial S_0}{\partial t} - \frac{\partial S_0}{\partial t} \frac{\partial S_0}{\partial t} \right) \alpha \beta \right\},$$

$$I_{L}^{(od, od)} = \frac{e}{h} \int_0^\infty dE \int_0^\infty dt \left\{ f_0, R - f_{0, L} \right\},$$

$$\times \left( T_{LR} + \sum_{\alpha=1}^{N_L} \sum_{\beta=1}^{N_L} \frac{R}{|S_0|} \left( \frac{\partial S_0}{\partial t} \frac{\partial S_0}{\partial t} - \frac{\partial S_0}{\partial t} \frac{\partial S_0}{\partial t} \right) \alpha \beta \right\}.$$
relates to the symmetry with respect to the applied voltage (temperature) difference.

The currents $I_{L}^{(ev,ev)}$ and $I_{L}^{(od,ev)}$ are conventional pumped currents (with reservoirs being at the same conditions). They depend on the asymmetry of the stationary scattering matrix: The phases $\theta$ and $\phi$ describe the asymmetry in the reflection from and in the transmission through the scatterer, respectively.

The remaining two contributions, $I_{L}^{(ev,od)}$ and $I_{L}^{(od,od)}$, are present if the electron flows incoming from the reservoirs are different. The even in magnetic field current $I_{L}^{(ev,ev)}$ exists already in the stationary case. The variation of the scattering parameters results in averaging over the time period and in the correction to the frozen conductance. In contrast the odd in magnetic field current $I_{L}^{(od,od)}$ exists only in the non-stationary regime.

The contributions $I_{L}^{(ev,ev)}$, $I_{L}^{(ev,od)}$, $I_{L}^{(od,ev)}$, and the part (proportional to $\partial \gamma / \partial t$) of $I_{L}^{(ev,od)}$ all are due to the quantum rectification of ac currents, Eq. (27), generated by the oscillating scatterer. This mechanism does work (i.e., a dc current already in the stationary case. The variation of the scattering matrix $\hat{S}_{\text{in}}/\hat{S}_{\text{out}}$, Eq. (34b), to be non-vanishing, (which requires that the integral over the time period is non-zero), are generally the same as that for, e.g., $I_{L}^{(ev,ev)}$, Eq. (34).

However, we emphasize that the necessary conditions to get a pumped current include both the time reversal symmetry breaking and the presence of a spatial asymmetry. Strictly speaking these conditions are not identical for all the parts, Eqs. (35) - (37). In particular, the applied voltage $V$ makes the whole system (the sample plus reservoirs) to be spatially non-symmetric, in the sense that the direction from the left to the right is not identical to the opposite direction. Therefore, e.g., the current $I_{L}^{(od,od)}$ is less sensitive to the spatial asymmetry of a scatterer than, e.g., the current $I_{L}^{(od,ev)}$ is.

In the next section we calculate the residual Floquet matrix $\hat{A}$ for several simple examples and illustrate the validity of the general statements made here. In particular we consider a one-dimensional loop with two leads and with enclosed magnetic flux. This example shows that the current $I_{L}^{(od,od)}$ exists (at nonzero magnetic flux) already if only the time reversal invariance is broken (i.e., if two parameters oscillate with a phase lag $\Delta \varphi \neq 0$). In contrast, a non-zero current $I_{L}^{(od,ev)}$ requires (in addition to $\Delta \varphi \neq 0$) an asymmetry in coupling to the leads. If such a coupling is symmetric then the current $I_{L}^{(od,ev)}$ is identically zero no matter how much the magnetic flux through the ring is and whether $\Delta \varphi$ is zero or not.

IV. THE FLOQUET SCATTERING MATRIX FOR LOW DRIVING FREQUENCIES: SIMPLE EXAMPLES

In this section we illustrate how one can calculate the linear in $\omega$ corrections to the frozen scattering matrix in the same fashion as the stationary scattering matrix $\hat{S}_{0}$.

According to Eq. (12), at $\omega \to 0$ the Floquet scattering matrix elements are the Fourier coefficients of some matrices $\hat{S}_{\text{in}}/\hat{S}_{\text{out}}$, Eq. (11) which depend on the stationary scattering matrix $\hat{S}_{0}$ and on the matrix $\hat{A}$. The matrix $\hat{S}_{\text{in}}/\hat{S}_{\text{out}}$ does not possess a definite symmetry, i.e., with respect to a time and/or a magnetic field direction reversal. While the stationary scattering matrix $\hat{S}_{0}$ and the matrix $\hat{A}$ do. The last circumstance is the motivation why we expressed the current $I_{0}$ in terms of $\hat{S}_{0}$ and $\hat{A}$ instead of $\hat{S}_{\text{in}}/\hat{S}_{\text{out}}$. On the other hand for the calculation of the Floquet scattering matrix elements it is more convenient to work in terms of the matrix $\hat{S}_{\text{in}}$ or $\hat{S}_{\text{out}}$.

A. Single $\delta$-function barrier

In the first example we consider the Floquet scattering matrix in the limit $\omega \to 0$ of an oscillating point-like scatterer coupled to two reservoirs via one-channel leads. As we will show for such a scatterer

$$\hat{A} = 0,$$  \hspace{1cm} (35)

and low frequency scattering up to linear in $\omega$ terms is entirely described by the frozen scattering matrix $\hat{S}_{0}(t)$, see Eqs. (12) and (11) at $\hat{A} = 0$.

To find $\hat{S}_{F}$ we have to solve the Schrödinger equation with the potential $V(x,t)$ being the delta function $\delta(x)$ multiplied by the amplitude oscillating in time:

$$i\hbar \frac{\partial \Psi}{\partial t} = \left( -\frac{\hbar^{2}}{2m_{e}} \frac{\partial^{2}}{\partial x^{2}} + V(x,t) \right) \Psi,$$

$$V(x,t) = \delta(x) \left( V_{0} + 2V_{1} \cos(\omega t + \varphi) \right).$$  \hspace{1cm} (36)

According to the Floquet theorem the solution of the above equation has the form of Eq. (6). Away from the point $x = 0$ the functions $\psi(E_{n})$ are the plain waves:

$$\psi(E_{n}) = a_{n} e^{i k_{n} x} + b_{n} e^{-i k_{n} x}.$$  \hspace{1cm} (37)

The coefficients $a_{n}$, $b_{n}$ are determined from the boundary condition at $x = 0$:

$$\Psi(x = +0) = \Psi(x = -0),$$

$$\Psi(x = +0) = \Psi(x = -0),$$

$$\frac{\partial \Psi}{\partial x} \big|_{x=0} - \frac{\partial \Psi}{\partial x} \big|_{x=0} = \frac{2 m_{e}}{\hbar^{2}} V(t) \Psi(x = 0).$$  \hspace{1cm} (38)

First, to find $S_{F,LL}$ and $S_{F,RL}$ we consider the plain wave of a unit amplitude with energy $E$ coming from the left (we directed the $x$-axis from the left to the right):

$$\Psi^{(in)}(E,t) = e^{-i \frac{\hbar^{2}}{2 m_{e}} k_{n} x}.$$  \hspace{1cm} (39)

Here $E = \hbar^{2} k^{2} / (2 m_{e})$. Then the coefficients $a_{n}^{(out)}$ and $b_{n}^{(out)}$ for an outgoing wave

$$\psi^{(out)} = e^{-i \frac{\hbar^{2}}{2 m_{e}} k_{n} x} \sum_{\theta} e^{-i \Delta \varphi n \omega t} \left( \theta(x) a_{n}^{(out)} e^{i k_{n} x} + \theta(-x) b_{n}^{(out)} e^{-i k_{n} x} \right),$$  \hspace{1cm} (40)
Here we have introduced the following parameters:

\[
S_{F,RL}(E_n, E) = \sqrt{\frac{k_{n}a_{n}^{(out)}}{k_{b_{n}^{(out)}}}}, \quad S_{F,LL}(E_n, E) = \sqrt{\frac{k_{b_{n}^{(out)}}}{k_{n}a_{n}^{(out)}}}.
\] (41)

Substituting the whole wave function \(\Psi = \Psi^{(in)} + \Psi^{(out)}\) into the boundary condition Eq. (39) we get the following relations between the different \(a_{n}^{(out)}\) and \(b_{n}^{(out)}\):

\[
(k_n + i\kappa_n)a_{n}^{(out)} = k_n\delta_{n0} - i(k_1a_{n-1}^{(out)} + \kappa_{-1}a_{n+1}^{(out)}),
\]
\[
b_{n}^{(out)} = a_{n}^{(out)} - \delta_{n0}.
\] (42)

Here we have introduced the following parameters:

\[
k_0 = \frac{m_e}{\hbar^2}V_0, \quad \kappa_{\pm} = \frac{m_e}{\hbar^2}V_0 e^{\mp i\phi}.
\] (43)

We solve Eq. (42) in the adiabatic limit \(\omega \to 0\) of interest here. In this limit we can safely expand the wave vector \(k_n\) as follows:

\[
k_n = k + \frac{\hbar\omega}{v} + O(\omega^2),
\] (44)

where \(v = \hbar k/m_e\) is an electron velocity. In addition we use the adiabatic expansion Eq. (43) and express \(\hat{S}_F(E_n, E)\) in terms of the Fourier coefficients of the matrix \(\hat{S}_n(E)\). Substituting Eqs. (11), (12) and (13) into Eq. (12), and ignoring all the terms of order \(\omega^2\) and higher we can write:

\[
(k + i\kappa_0)S_{n,RL,n} + \left(\frac{\hbar\omega}{v} - i\kappa_0\right)S_{n,LL,n} = \delta_{n0} - i(k_1S_{n-1,RL,n} + \kappa_{-1}S_{n,RL,n+1}) + \sqrt{\frac{\kappa_0}{\kappa_{\pm}}}k_{\pm}[n(n-1)S_{n,RL,n-1} + \kappa_{-1}(n+1)S_{0,RL,n+1}],
\]
\[
S_{n,LL,n}(E) = S_{n,RL,n}(E) - \delta_{n0}\sqrt{\frac{\kappa_0}{\kappa_{\pm}}}.
\]

Performing the inverse Fourier transformation we find the equation for the time-dependent matrix elements of the matrix \(\hat{S}_n(E, t)\):

\[
S_{n,RL}(E, t) = \frac{k}{k_0 + i\kappa(t)} - i \frac{\kappa}{2k_0 + i\kappa(t)} \delta_{n0}S_{0,RL,E}(t),
\]
\[
S_{n,LL}(E, t) = S_{n,RL}(E, t) - 1.
\] (45)

Here \(\kappa(t) = m_eV(t)/\hbar^2\). We solve these equations perturbatively in the small parameter proportional to \(\partial/\partial t \sim \omega \to 0\). To find the matrix elements \(S_{n,RL}\) and \(S_{n,LR}\) one can either exploit the symmetry condition or solve the same problem but with the unit wave incoming from the right: \(\Psi^{(in)}(E) = e^{-i\Phi(x,t)}e^{-ik_0x}\). Up to terms linear in \(\omega\), the solution of both problems reads:

\[
\hat{S}_n(E, t) = \hat{S}_0(E, t) + \frac{i\hbar}{2} \partial^2 \hat{S}_0(E, t) / \partial t \partial E.
\] (46)

Here we used \(\partial k / \partial E = 1/(\hbar v)\). The stationary matrix is well known:

\[
\hat{S}_0 = \frac{k}{k + i\kappa} \left( \begin{array}{cc} 1 & 1 \\ 1 & 1 \end{array} \right) - \hat{I}.
\] (47)

Comparing equations (46) and (47) we arrive at the announced result, Eq. (38). Thus, to describe the low frequency scattering on point-like scatterer it is enough to know only the frozen scattering matrix.

Alternatively, one can use Eq. (1) to show that the matrix \(\hat{A}\) vanishes for the oscillating \(\delta\)-function potential. It is because the commutator \([\hat{S}_0, \hat{S}_0]\) is identically zero for the scattering matrix Eq. (47). We can conclude that a point scatterer cannot generate a quantum pump effect since it can not rectify ac currents (the spectral density \(dI_{ac}/dE\), Eq. (24), vanishes). An oscillating scatter does of course generate currents, but these currents are total time derivatives of the charge near the barrier\(23\) and thus can not contribute to a dc-current.

Note, that the deviation of the effective scattering matrix \(\hat{S}_{n}(E, t)\), Eq. (10) from the frozen scattering matrix \(\hat{S}_0(E, t)\), Eq. (17), is as small as, at least, \(\hbar \omega / E\). For the opaque barrier the deviation is even smaller due to the factor \(k/\kappa \ll 1\). For the small oscillating amplitude case the deviation is additionally damped by the factor \(k_1/\kappa_0 \ll 1\).

**B. Scattering composed of two point-like barriers**

In this subsection we consider an example of a spatially "extended" scatterer which consists of two point-like scatterers placed at \(x = 0\) and \(x = L\), respectively. This system is coupled to two reservoirs via single channel leads.

The scattering properties of point scatterers are assumed to be oscillating in time with the same frequency \(\omega\). Scattering at the left and on the right barriers is described via the Floquet scattering matrices \(\hat{S}^F_{F,RL}\) and \(\hat{S}^F_{F,LL}\), respectively. Scattering on the whole system is described via the Floquet scattering matrix \(\hat{S}^F_F\).

By analogy with the previous example we consider scattering of a unit wave coming from the left, Eq. (10). The whole wave function is of a Floquet function type Eq. (4) with

\[
\psi(E_n) = \left\{ \begin{array}{ll} \delta_{n0} e^{ik_0x} + \sqrt{\frac{k_0}{\kappa_0}}S_{F,LL}(E_n, E) e^{-ik_0x}, & x < 0, \\ a_{n0} e^{ik_0x} + b_{n} e^{-ik_0x}, & 0 < x < L, \\ \sqrt{\frac{k_0}{\kappa_0}}S_{F,RL}(E_n, E) e^{ik_0(x-L)}, & x > L. \end{array} \right.
\] (48)

To find the unknown coefficients we use the boundary conditions which we formulate in terms of scattering matrices \(\hat{S}^F_{F,RL}\) and \(\hat{S}^F_{F,LL}\) assumed to be known:

\[
S_{F,LL}(E_n, E) = S^F_{F,LL}(E_n, E) + \sum_m S^F_{F,RL}(E_n, E_m) \sqrt{\frac{k_m}{\kappa_m}} b_m,
\]
\[
S_{F,RL}(E_n, E) = S^F_{F,RL}(E_n, E) + \sum_m S^F_{F,LL}(E_n, E_m) \sqrt{\frac{k_m}{\kappa_m}} a_m e^{ik_m x},
\]
\[
\frac{k_0}{\kappa_0} a_n = S^F_{F,RL}(E_n, E) + \sum_m S^F_{F,RR}(E_n, E_m) \sqrt{\frac{k_m}{\kappa_m}} b_m,
\]
\[
\frac{k_0}{\kappa_0} b_n e^{-ik_0 L} = \sum_m S^F_{F,LL}(E_n, E_m) \sqrt{\frac{k_m}{\kappa_m}} a_m e^{ik_m L},
\]
\[
S_{F,RL}(E_n, E) = \sum_m S^F_{F,RL}(E_n, E_m) \sqrt{\frac{k_m}{\kappa_m}} a_m e^{ik_m L},
\] (49)

To simplify this system of equations we use the adiabatic approximation Eq. (13) for the Floquet scattering matrices. For this approximation to be valid, the energy quantum \(\hbar \omega\) should be small compared with the relevant energy scale for the problem, [see Eq. (9)].

In the case under consideration, there are several energy scales. The first one is determined by the energy \(E\) of an incoming electron. This scale relates to the deviation of the effective scattering matrices \(\hat{S}^F_{F,RL}\) and \(\hat{S}^F_{F,LL}\) for point-like scatterers from the corresponding frozen ones. This deviation is of the order of \(\hbar \omega / E\). Another energy scale \(\delta E\) relates to the spatial size of the system \(L\) and arises from the quantum
mechanical interference in the region between the scatterers at \(0 < x < L\). In our case, Eq. (11), the interference effect is described via the factors \(e^{ik_mL}\) which will expand as follows:

\[
e^{\pm i k_m L} = e^{\pm i k L} \left( 1 \pm i m \frac{\omega}{\omega_L} + O(\omega^2) \right). \tag{50}
\]

Here \(\omega_L = v/L\) defines the distance \(\Delta E \sim \hbar \omega_L\) between the quantum levels if the system is decoupled from the reservoirs. The second term in the brackets on the RHS of Eq. (50) is due to an interplay of a quantum-mechanical interference with a quantized energy exchange between the scatterer and an electron traversing it.

The system can be treated as spatially "extended" if \(L \gg \lambda_E\), where \(\lambda_E = \hbar / \sqrt{2 m \omega E}\) is the de Broglie wave length for an electron with energy \(E\). In such a case the non-adiabatic corrections to the frozen scattering matrix are at least of order \(\hbar \omega / \Delta E\). Note if the energy \(E\) is close to the energy of a transmission resonance then the corrections will be of order \(\hbar \omega / \Gamma\), where \(\Gamma\) is the width of the transmission resonance. In contrast, if \(L \lesssim \lambda_E\) then the scatterer can be viewed as point-like and the non-adiabatic corrections will be as small as \(\hbar \omega / E\) (see, Sec. [\ref{V}]). Therefore, assuming \(L \gg \lambda_E\) we can safely ignore the corrections of order \(\hbar \omega / E\) and concentrate on the larger corrections of order \(\hbar \omega / \Delta E\) with \(\delta E = \min(\{\Delta E, \Gamma\})\). Since we ignore the terms of order \(\hbar \omega / E\) we can replace the Floquet scattering matrices for point-like scatterers by the corresponding frozen scattering matrices, \(S^{R/L}_F(E_n, E_m) = \hat{S}^{R/L}_{\text{in},m} + O(\hbar \omega / E)\) [see, Eq. (5)]. To avoid a possible misunderstanding we do not write the energy \(E\) as an argument of \(\hat{S}^{R/L}\) emphasizing that these matrices can be treated as energy independent on the scale of \(\delta E\). Nevertheless they can depend on energy over a much larger scale, say, of order \(E\). On the other hand, since we keep the terms of order \(\hbar \omega / \delta E\) we use the adiabatic approximation \(\hat{S}_F(E_n, E) = \hat{S}_{\text{in},n}(E) + O(\omega^2)\) [see, Eq. (12)] for the Floquet scattering matrix of the whole structure.

Using these approximations and substituting Eq. (50) into the system of equations (19) and performing the inverse Fourier transformation we arrive at the following time-dependent equations valid up to first order in \(\partial / \partial t\):

\[
S_{\text{in},LL}(E, t) = \hat{S}^L_{\text{in},LL}(t) + S^R_{0,RR}(t) b(t),
\]

\[
a(t) = S^L_{0,RR}(t) + S^R_{0,RL}(t) b(t),
\]

\[
e^{-ikL} \left( b(t) + \frac{1}{e_L} \frac{\partial b(t)}{\partial t} \right) = S^R_{0,LL}(t) e^{ikL} \left( a(t) - \frac{1}{e_L} \frac{\partial a(t)}{\partial t} \right),
\]

\[
S_{\text{in},RL}(E, t) = S^R_{0,RL}(t) e^{ikL} \left( a(t) - \frac{1}{e_L} \frac{\partial a(t)}{\partial t} \right). \tag{51}
\]

Here we introduced the functions \(a(t)\) and \(b(t)\) defined as follows \((x = a, b)\):

\[
x(t) = \sum_{n} e^{-i n \omega t} \sqrt{\frac{n}{K}} x_n. \tag{52}
\]

We consider the terms \(\partial a / \partial t\) and \(\partial b / \partial t\) as small perturbations and solve the system of equations (51) up to linear order in these corrections terms.

Note, that without the terms \(\partial a / \partial t\) and \(\partial b / \partial t\) the system of equations Eq. (51) is exactly the system of equations which defines the matrix elements of the frozen (stationary) scattering matrix (with the evident replacement \(\hat{S}_{\text{in}} \rightarrow \hat{S}_0\)).

Analogously, to calculate \(S_{\text{in},RR}\) and \(S_{\text{in},LR}\) we consider the same problem but with the unit wave coming from the right:

\[
\psi^{(in)}(x, t) = e^{-ik(x-L)} \xi(t). \tag{53}
\]

It is convenient to represent the results in the matrix form:

\[
\hat{S}_{\text{in}}(E, t) = \hat{S}_0 - \frac{1}{\omega_L} \hat{M}_L \hat{M}^{-1} \frac{\partial}{\partial t} \left[ \hat{M}^{-1} \hat{M}_R \right]. \tag{54}
\]

Here \(\hat{S}_0\) is the frozen scattering matrix:

\[
\hat{S}_0(E, t) = \hat{M}_0 + \hat{M}_L \hat{M}^{-1} \hat{M}_R. \tag{55}
\]

The matrices \(\hat{M}_L\) and \(\hat{M}_R\) are all expressed in terms of the scattering matrix elements for the left and right scatterers. They depend on energy through the factor \(e^{ikL}\) and on time through the matrices \(\hat{S}^L_0\) and \(\hat{S}^R_0\):

\[
\hat{M}_0 = \begin{pmatrix} S^L_{0,LL} & 0 \\ 0 & S^R_{0,RR} \end{pmatrix}, \quad \hat{M}_L = \begin{pmatrix} 0 & S^L_{0,RL} e^{ikL} \\ S^R_{0,RL} e^{-ikL} & 0 \end{pmatrix}, \quad \hat{M}_R = \begin{pmatrix} S^R_{0,RL} & 0 \\ 0 & S^L_{0,RL} e^{ikL} \end{pmatrix}. \tag{56}
\]

Our aim is to calculate the matrix

\[
\hbar \omega \hat{A} = \hat{S}_{\text{in}} - \hat{S}_0 - \frac{i \hbar}{2} \frac{\partial^2 \hat{S}_0}{\partial \omega \partial E}. \tag{57}
\]

[see, Eq. (19)] for the double scatterer structure under consideration. Using Eq. (53) we obtain

\[
\hbar \omega \hat{A}(E, t) = \frac{1}{2 e_L} \frac{\partial}{\partial t} \left[ \hat{M}_L \hat{M}^{-1} \hat{M}^{-1} \hat{M}_R \right]. \tag{58}
\]

The advantage of the above expression is its compactness. However to be able to draw some conclusion we need the matrix elements of \(\hat{A}\) expressed directly in terms of the matrix elements of \(S^L_0\) and \(S^R_0\):

\[
\hbar \omega A_{LL} = \frac{S^L_{0,LL} - S^R_{0,LL}}{\omega_L} \frac{\partial}{\partial \omega} \left[ \ln \left( \frac{S^L_{0,LL}}{S^R_{0,RL}} \right) \right],
\]

\[
\hbar \omega A_{LR} = \frac{S^L_{0,LL}}{\omega_L} \left\{ (2 \Delta) \frac{\partial}{\partial \omega} \ln \left( \frac{S^L_{0,RL}}{S^R_{0,RL}} \right) + (1 - \Delta) \frac{\partial}{\partial \omega} \ln \left( \frac{S^L_{0,RL}}{S^R_{0,RL}} \right) \right\}, \tag{59}
\]

\[
\hbar \omega A_{RL} = \frac{S^L_{0,RR}}{2 \omega_L} \left\{ (2 \Delta) \frac{\partial}{\partial \omega} \ln \left( \frac{S^L_{0,RL}}{S^R_{0,RL}} \right) + (1 - \Delta) \frac{\partial}{\partial \omega} \ln \left( \frac{S^L_{0,RL}}{S^R_{0,RL}} \right) \right\}, \tag{60}
\]

\[
\hbar \omega A_{RR} = \frac{S^L_{0,RR} - S^R_{0,RR}}{\omega_L} \frac{\partial}{\partial \omega} \ln \left( \frac{S^R_{0,RR}}{S^L_{0,RL}} \right). \tag{61}
\]

Here \(\Delta = 1 - S^L_{0,RR} S^R_{0,RL} e^{i k L}\). We see that for the case considered the matrix elements of \(\hat{A}\) are proportional to time derivatives as it should be.
C. Ring with enclosed magnetic flux

Our third example is a one-channel ring with enclosed magnetic flux Φ coupled to two reservoirs, Fig. 1. The lower and the upper branches of the ring have length \(L_1\) and \(L_2\), respectively. Following Ref. 5 we describe the coupling between the ring and the lead via a single parameter 3 \(\times\) 3 scattering matrix \(S_0(\epsilon)\), with \(\epsilon = \epsilon^L\) and \(\epsilon = \epsilon^R\) for the left and the right coupling points, respectively. The numbering of scattering channels is shown in Fig. 1. We will use two different matrices, \(\tilde{S}_0^{(a)}\) and \(\tilde{S}_0^{(\alpha)}\), which couple the lead to the branches of the ring symmetrically and asymmetrically, respectively. They are:

\[
\tilde{S}_0^{(a)}(\epsilon) = \begin{pmatrix} -a + b & \sqrt{\epsilon} & \sqrt{\epsilon} \\ \sqrt{\epsilon} & a & b \\ \sqrt{\epsilon} & b & a \end{pmatrix},
\]

(58a)

\[
\tilde{S}_0^{(\alpha)}(\epsilon) = \begin{pmatrix} a & \sqrt{\epsilon} & -(a + b) \\ \sqrt{\epsilon} & -a - b & \sqrt{\epsilon} \\ b & \sqrt{\epsilon} & a \end{pmatrix}.
\]

(58b)

Here \(a = (\sqrt{1 - 2\epsilon} - 1)/2\) and \(b = (\sqrt{1 - 2\epsilon} + 1)/2\). The coupling parameter should be within the following interval: \(0 \leq \epsilon \leq 0.5\). We suppose that the coupling parameters \(\epsilon^L\) and \(\epsilon^R\) oscillate in time with the same frequency \(\omega\) but with the phase lag \(\Delta\phi = \varphi^R - \varphi^L\):

\[
\epsilon^L/R = [\epsilon^L/R + \epsilon^L/R \cos(\omega t + \varphi^L/R)]/2.
\]

We keep the parameters \(\epsilon^L\) and \(\epsilon^R\) independent of the electron energy. This allows us to describe the time-dependent scattering at the three lead splitters within the frozen scattering matrix approximation, see Sec.II A. Also we assume that a voltage \(V\) can be applied between the reservoirs, here kept at the same temperature, see Eq. 52.

We concentrate mainly on the part of the current \(I_{L}^{(od,od)}\) which is odd in magnetic flux \(I_{L}^{(od,ev)}\) and \(I_{L}^{(od,od)}\), Eqs. 54 and 55, are given as a function of the phase difference \(\Delta\phi = \varphi^R - \varphi^L\) between the oscillating coupling parameters \(\epsilon^R(t)\) and \(\epsilon^L(t)\) for symmetric coupling: Both the left and the right wave splitters are coupled symmetrically to the branches of the ring. The currents are in units of \(\epsilon_0/(2\pi)\). The parameters are:

\(L_1 = \pi; L_2 = 0.7\pi; \Phi = 0.4\Phi_0; \mu_0 = 9; V = 0.5; T_L = T_R = 0.1; \epsilon_0^L = \epsilon_0^R = 0.5; \epsilon_1^L = \epsilon_1^R = 0.4\). We use the following units: \(2m_e = 1; \hbar = 1; e = 1; k_B = 1\).

![FIG. 1: A one-channel ring of length \(L = L_1 + L_2\) with enclosed magnetic flux Φ and with two leads. The Greek letter α numbers the scattering channels at the left \(S^L\) and right \(S^R\) wave splitters.](image1)

![FIG. 2: The parts of the pumped currents which are odd in magnetic flux \(I_{L}^{(od,ev)}\) and \(I_{L}^{(od,od)}\), Eqs. 54 and 55, are given as a function of the phase difference \(\Delta\phi = \varphi^R - \varphi^L\) between the oscillating coupling parameters \(\epsilon^R(t)\) and \(\epsilon^L(t)\) for symmetric coupling: Both the left and the right wave splitters are coupled symmetrically to the branches of the ring. The currents are in units of \(\epsilon_0/(2\pi)\). The parameters are:

\(L_1 = \pi; L_2 = 0.7\pi; \Phi = 0.4\Phi_0; \mu_0 = 9; V = 0.5; T_L = T_R = 0.1; \epsilon_0^L = \epsilon_0^R = 0.5; \epsilon_1^L = \epsilon_1^R = 0.4\). We use the following units: \(2m_e = 1; \hbar = 1; e = 1; k_B = 1\).](image2)

![FIG. 3: The currents \(I_{L}^{(od,ev)}\) and \(I_{L}^{(od,od)}\) in units of \(\epsilon_0/(2\pi)\)](image3) as a function of the enclosed magnetic flux Φ in units of the magnetic flux quantum \(\Phi_0 = h/e\) for the case of symmetric coupling: Both the left and the right wave splitters are coupled symmetrically to the branches of a ring. The parameters are the same as in Fig. 2. The phase difference is: \(\Delta\phi = \pi/2\).
and \( \phi \) respectively. To find \( I^{(\text{od,od})} \) it is necessary to calculate the residual Floquet matrix \( \hat{A} \) for the system under consideration, Fig. 2. These calculations are quite similar to those given in Sec. V.B and we do not give the details here, see Appendix.

The current \( I_L^{(\text{od,ev})} \), odd in magnetic flux and even in applied voltage, is governed by the phase \( \phi \) which determines the asymmetry in the transmission phase through the ring, see Eq. (31). Interestingly, in our model this asymmetry depends crucially on the type of coupling between the leads and the ring. If each of the leads is coupled symmetrically to the arms of the ring, i.e., if \( \hat{S}_R^{(a)} = \hat{S}_0^{(a)}(e^R) \) and \( \hat{S}_R^{(a)} = \hat{S}_0^{(a)}(e^R) \), then the phase \( \phi \) is 0 for any magnetic flux. In such a case the current \( I_L^{(\text{od,ev})} \) is identically zero and the full current odd in magnetic flux \( I_L^{(\text{od})} \) is odd in the applied voltage as well.

In Fig. 2 and Fig. 3 we depict the current contribution which is odd in magnetic flux as a function of the phase lag and the magnetic flux, respectively, for symmetric coupling. Thus if the coupling between the ring and the leads is symmetric the current odd in magnetic flux appears only at \( V \neq 0 \) (and/or at \( \Delta T \neq 0 \)), i.e., when the electron flows incident on the ring from the reservoirs are different. In contrast, if any lead (or both) is coupled asymmetrically to the ring, i.e., if \( \hat{S}_R^{(a)} = \hat{S}_0^{(a)}(e^L) \) and/or \( \hat{S}_R^{(a)} = \hat{S}_0^{(a)}(e^L) \), then the phase \( \phi \) is not identically zero and the current \( I_L^{(\text{od,ev})} \) does contribute to \( I_L^{(\text{od})} \).

In Fig. 4 we depict the currents \( I_L^{(\text{od,ev})} \) and \( I_L^{(\text{od,ev})} \) as a function of the Fermi energy \( \mu_0 \) for asymmetric coupling. For comparison we give the current \( I_L^{(\text{ev,od})} \), Eq. (31), which is proportional to the transmission probability through the ring. Both currents \( I_L^{(\text{od,ev})} \) and \( I_L^{(\text{od,od})} \) peak (by modulo) at energies where the transmission (reflection) coefficient changes sharply.

V. CONCLUSION

In this work we analyze the scattering properties of a periodically driven mesoscopic scatterer. Traversing such a scatterer an electron can gain or lose one or several energy quanta \( h\omega \) and thus can change its energy. Therefore, generally the scattering matrix of a periodically driven mesoscopic scatterer depends on two energies, incoming and outgoing. We show that at low driving frequency \( \omega \to 0 \) one can introduce effective matrices depending on only one energy, either incoming or outgoing [see, Eq. (11)], which approximates accurately the Floquet scattering matrix up to terms of order \( \omega \) [see, Eq. (12)]. We introduce two effective matrices, \( \hat{S}_\text{in} \) and \( \hat{S}_\text{out} \), which are not unitary. Nevertheless each of them conserves the current after averaging over a driving cycle.

The matrices \( \hat{S}_\text{in} \) and \( \hat{S}_\text{out} \) are the sum of a frozen scattering matrix and a matrix which determines the linear in \( \omega \) part. The last is responsible for the quantum pump effect and it consists of two contributions. The first one is the second derivative of the frozen scattering matrix \( \hat{S}_0(t) \). The second contribution is defined by an in principle new matrix \( \hat{A} \). In particular, the matrix \( \hat{A} \) has a symmetry with respect to magnetic field reversal, Eq. (23), that is opposite to that of the stationary (frozen) scattering matrix, Eq. (17). In contrast to the stationary scattering matrix the residual Floquet matrix reflects directly the chirality of the pumping process.

Using the adiabatic representation Eq. (12) for the Floquet scattering matrix we examine the dc current flowing through the two terminal (many channels) mesoscopic sample under the simultaneous action of a slow parametric oscillation of the scatterer and simultaneously subject to an applied dc voltage. We divide the current into parts with definite symmetry properties with respect to a magnetic field and/or a voltage inversion.

As it is known in the stationary case the dc current through the coherent two terminal sample is an even function of a magnetic field. On the other hand the periodically driven scatterer shows an odd in magnetic field, linear in \( \omega \) current, Eq. (31), which is due to the quantum pump effect. The odd in applied voltage part of this current is proportional to the residual Floquet matrix \( \hat{A} \) [see also, Eq. (32)].

We demonstrate that the calculation of the residual matrix \( \hat{A} \) can be performed in close analogy with the calculation of the stationary scattering matrix \( \hat{S}_0 \). We emphasize that the matrix \( \hat{A} \) reflects the interplay of absorbing/emitting of energy quanta \( h\omega \) with quantum mechanical interference inside the scatterer. For instance, for a point-like scatterer (without the space for interference inside) the matrix \( \hat{A} \) is identically zero.

Our work suggests that additional experiments which investigate a driven mesoscopic conductor in a less symmetric setup, i.e., with reservoirs having different electrochemical potentials or temperatures, might be useful to reveal the presence of a quantum pump effect.

Ring with enclosed magnetic flux: Analytical expressions

The stationary scattering matrix $\hat{S}_0$ for the ring with branches of length $L_1$ and $L_2$, and with enclosed magnetic flux $\Phi$ coupled to two leads via wave splitters $S^L$ and $S^R$ (see, Fig. 1) reads:

$$\hat{S}_0 = \begin{pmatrix} S_{0,LL} & S_{0,LR} \\ S_{0,RL} & S_{0,RR} \end{pmatrix},$$

$$S_{0,LL} = S_{11}^L + S_{12}^L W_2 + S_{13}^L W_3 e^{iL_2 (\frac{2\Phi}{\hbar} + \frac{\Phi}{\hbar})},$$

$$S_{0,RL} = S_{11}^R W_4 + S_{12}^R W_1 e^{iL_1 (\frac{2\Phi}{\hbar} + \frac{\Phi}{\hbar})},$$

$$S_{0,LR} = S_{12}^L W_4' + S_{13}^L W_1' e^{iL_2 (\frac{2\Phi}{\hbar} + \frac{\Phi}{\hbar})},$$

$$S_{0,RR} = S_{11}^R + S_{12}^R W_2' + S_{13}^R W_3' e^{iL_1 (\frac{2\Phi}{\hbar} + \frac{\Phi}{\hbar})}.$$

Here $L = L_1 + L_2$; $\Phi_0 = h/e$ is the single-electron magnetic flux quantum. The vector-columns $\hat{W}$ and $\hat{W}'$ are defined in the following way:

$$\hat{W} = \hat{M}^{-1} \hat{Y},$$

$$\hat{W}' = \hat{M}'^{-1} \hat{Y'},$$

$$\hat{Y} = \begin{pmatrix} -S_{11}^L \\ -S_{12}^L \\ 0 \\ 0 \end{pmatrix},$$

$$\hat{Y'} = \begin{pmatrix} -S_{11}^R \\ -S_{12}^R \\ 0 \\ 0 \end{pmatrix},$$

$$\hat{M} = \begin{pmatrix} -1 & S_{12}^L & S_{23}^L c[L_2, k] & 0 \\ 0 & S_{12}^L & S_{23}^L c[L_2, k] & -c[L_2, -k] \\ S_{23}^R c[L_1, k] & 0 & -1 & S_{22}^R \\ -c[L_1, -k] & S_{23}^R c[L_1, k] & S_{22}^R & 0 \end{pmatrix},$$

$$\hat{M}' = \begin{pmatrix} -1 & S_{12}^R & S_{23}^R c[L_1, k] & 0 \\ 0 & S_{12}^R & S_{23}^R c[L_1, k] & -c[L_1, -k] \\ S_{23}^L c[L_2, k] & 0 & -1 & S_{22}^L \\ -c[L_2, -k] & S_{23}^L c[L_2, k] & S_{22}^L & 0 \end{pmatrix}.$$

Here we introduced the functions $c[x, y] = e^{ix (\frac{2\Phi}{\hbar} + \frac{\Phi}{\hbar}) + iy}$. The anti-symmetric matrix $\hat{A}$ characterizing the ability of the ring with oscillating coupling parameters $\epsilon^L(t)$ and $\epsilon^R(t)$ [see, Eqs. (58)] to work as a pump is:

$$\hbar \omega \hat{A} = \hat{a} - \frac{\partial^2 \hat{a}}{\partial t^2},$$

$$\hat{a} = \begin{pmatrix} a_{LL} & a_{LR} \\ a_{RL} & a_{RR} \end{pmatrix},$$

$$a_{LL} = S_{12}^L \delta W_2 + S_{13}^L \left( \delta W_3 - \frac{1}{\omega_{L_2}} \frac{\partial W_3}{\partial t} \right) e^{iL_2 (\frac{2\Phi}{\hbar} + \frac{\Phi}{\hbar})},$$

$$a_{RL} = S_{12}^R \delta W_4 + S_{13}^R \left( \delta W_1 - \frac{1}{\omega_{L_1}} \frac{\partial W_1}{\partial t} \right) e^{iL_1 (\frac{2\Phi}{\hbar} + \frac{\Phi}{\hbar})},$$

$$a_{LR} = S_{12}^L \delta W_4' + S_{13}^L \left( \delta W_1' - \frac{1}{\omega_{L_2}} \frac{\partial W_1'}{\partial t} \right) e^{iL_2 (\frac{2\Phi}{\hbar} + \frac{\Phi}{\hbar})},$$

$$a_{RR} = S_{12}^R \delta W_2' + S_{13}^R \left( \delta W_3' - \frac{1}{\omega_{L_1}} \frac{\partial W_3'}{\partial t} \right) e^{iL_1 (\frac{2\Phi}{\hbar} + \frac{\Phi}{\hbar})}.$$
