Neutrophil depletion—but not prevention of Kupffer cell activation—decreases the severity of cerulein-induced acute pancreatitis

Catherine M Pastor, Alain Vonlaufen, Fabianna Georgi, Antoine Hadengue, Philippe Morel, Jean-Louis Frossard

INTRODUCTION

During acute pancreatitis, the pathophysiology of pancreatic injury includes inflammatory processes and, following early activation of trypsinogen in acinar cells, recruitment of inflammatory cells aggravates pancreatic damage[1,2]. Upon activation, circulating inflammatory cells adhere to vascular endothelial cells and transmigrate across the endothelial barrier within injured areas in pancreas as well as in remote organs. Thus, mice deficient in adhesion molecules such as intercellular adhesion molecule 1 (ICAM-1)[3], or animals treated with an antineutrophil serum (ANS)[4] are protected from pancreatitis and remote injuries. However, the protection remained incomplete[4].

In contrast to the severe lung injury frequently associated with pancreatitis, hepatic injury is minor during acute pancreatitis[5]. Nevertheless, hepatic functions are modified by pancreatitis. Detoxification is altered early in the evolution of the disease[6,7] and this decreased hepatic detoxification is compensated by an increased detoxification in blood, lungs, and intestine macrophages[8]. Moreover, mediators released from the damaged pancreas directly activate Kupffer cells and promote important inflammatory responses in the liver.

METHODS: Mice had cerulein administration to induce acute pancreatitis and were pretreated with either anti-mouse neutrophil serum or gadolinium chloride (GdCl3) to prevent Kupffer cell activation, or both treatments. Injury was assessed in pancreas and lungs. Myeloperoxidases (MPO) assessed neutrophil infiltration. Interleukin-6 (IL-6) and IL-10 were measured in serum, pancreas, lungs and liver.

RESULTS: In mice with acute pancreatitis, neutrophil depletion reduced the severity of pancreatitis and pancreatitis-associated lung injury. Kupffer cell inactivation by GdCl3 had less protective effect, although IL-6 and IL-10 concentrations were significantly decreased. The protective treatment brought by neutrophil depletion was not enhanced by Kupffer cell inactivation and both treatments did not combine their protective effects.

CONCLUSION: Our results confirm the role of activated neutrophils in aggravating organ injury in acute pancreatitis while the role of Kupffer cell activation is less obvious.

INTRODUCTION

During acute pancreatitis, the pathophysiology of pancreatic injury includes inflammatory processes and, following early activation of trypsinogen in acinar cells, recruitment of inflammatory cells aggravates pancreatic damage[1,2]. Upon activation, circulating inflammatory cells adhere to vascular endothelial cells and transmigrate across the endothelial barrier within injured areas in pancreas as well as in remote organs. Thus, mice deficient in adhesion molecules such as intercellular adhesion molecule 1 (ICAM-1)[3] on endothelial cells or animals treated with an antineutrophil serum (ANS)[4] are protected from pancreatitis and remote injuries. However, the protection remained incomplete[4].

In contrast to the severe lung injury frequently associated with pancreatitis, hepatic injury is minor during acute pancreatitis[5]. Nevertheless, hepatic functions are modified by pancreatitis. Detoxification is altered early in the evolution of the disease[6,7] and this decreased hepatic detoxification is compensated by an increased detoxification in blood, lungs, and intestine macrophages[8]. Moreover, mediators released from the damaged pancreas directly activate Kupffer cells and promote important inflammatory responses in the liver.
Elastase administration, either in the peritoneum or in perfused livers mimics this important inflammatory response. The role of the liver in acute pancreatitis is then to propagate pancreatic injury to lungs. Portocaval shunts (that dilute harmful pancreatic mediators in the systemic circulation) and inhibitors of Kupffer cell activation such as gadolinium chloride (GdCl$_3$) and liposome-encapsulated dichloromethylene diphosphonate (DMDP) decrease acute pancreatitis-associated-lung injury.

Because neutrophil depletion or prevention of Kupffer cell activation is only partially effective in decreasing the severity of acute pancreatitis, the aim of our study was to determine whether both treatments might combine their protective effects.

**MATERIALS AND METHODS**

**Animals**

Breeding pairs of C57BL6 mice were purchased from Charles River (Saint-Germain sur l’Arbresle, France) and bred and housed in temperature-controlled (23 ± 2°C) cages with a 12 h light/dark cycle. They were fed with standard laboratory chow, given water ad libitum, and randomly assigned to control or experimental groups. The experimental protocol was reviewed and approved by the Ethics Committee for Animal Research of the University of Geneva and the Veterinary Office in Geneva and followed the guidelines for care and use of laboratory animals.

**Induction of acute pancreatitis**

Male mice (20-22 g) were intraperitoneally injected hourly for 10 h (10 injections) with a supramaximally stimulating dose of cerulein (CER, 50 µg/kg in 0.2 mL saline solution) to elicit a secretagogue-induced pancreatitis. Cerulein, the analog of the pancreatic secretagogue cholecystokinin was purchased from Research Plus (Bayonne, NJ, USA). Control (CONT) mice were injected with saline solution. One hour after the final injection, mice were sacrificed by a lethal intraperitoneal injection of pentobarbital.

**Neutrophil depletion**

Twelve hour before the start of cerulein administration, mice were treated with 0.2 mL rabbit anti-mouse neutrophil serum (ANS, ip injection, Accurate Chemical and Scientific Corp, Westbury, NY) as previously described.

**Kupffer cell inactivation**

To prevent Kupffer cell activation, gadolinium chloride (GdCl$_3$, 1 mg/100 g of body weight, Sigma, Basel, Switzerland) was injected into mice tail vein 12 h and 1 h before the start of cerulein or saline administration. Another experimental group received both treatments.

**Experimental groups**

Five experimental groups were studied: CONT mice had saline injection and no treatment; CER mice had cerulein administration and were treated with saline; CER + ANS mice had cerulein administration and were treated with anti-mouse neutrophil serum; CER + GdCl$_3$ mice had cerulein administration and were treated with gadolinium chloride; CER + ANS + GdCl$_3$ mice had cerulein administration and were treated with ANS and GdCl$_3$.

**Quantification of cerulein-induced injuries**

At the time of sacrifice (1 h following the last cerulein injection), blood was collected from the heart, centrifuged for 10 min, and the serum was kept at -80°C until assayed. Serum amylase activity was measured using 4,6-ethylidene (G1)-p-nitrophenyl (G1)-αD-malto-heptoside (Sigma Chemical Company, St. Louis, Missouri) as substrate.

To quantify pancreatic edema, part of the pancreas was removed to measure tissue water content. Pancreatic tissue was weighed before and after desiccation at 95°C during 24 h. The difference between the wet and dry tissue weights was calculated and expressed as a percent of tissue wet weight. The other parts of pancreatic tissues were frozen in liquid nitrogen for cytokine measurements.

Neutrophil sequestration within pancreas was detected by measuring tissue myeloperoxidase activity (MPO) ($^{[13]}$). Pancreatic samples were thawed, homogenized in 1 mmol/L in 20 mmol/L phosphate buffer (pH 7.4), centrifuged (10000 g, 10 min), and the resulting pellet was resuspended in 50 mmol/L phosphate buffer (pH 6.0) containing 0.5% hexadecylmethylammonium bromide. The suspensions were subjected to four cycles of freezing and thawing and sonicated. The samples were centrifuged (10000 g, 5 min) and the supernatants were used to measure MPO activity. The reaction solution included 1.6 mmol/L tetramethylbenzidine (Sigma, Switzerland), 80 mmol/L sodium phosphate buffer (pH 5.4) and 0.3 mmol/L hydrogen peroxide (Sigma, Switzerland). Samples in solution were incubated at 37°C for 2 min and the absorbance was read by an autoanalyzer. MPO activity was expressed as U/mg tissue dry weight.

Pulmonary microvascular permeability was evaluated by quantitating the leakage of intravenously injected fluorescein isothiocyanate (FITC)-labeled bovine albumin (0.5 mg/kg in 0.2 mL) into the bronchoalveolar space (BAL) ($^{[14]}$). Immediately after sacrifice, the trachea was exposed and the lungs were injected three times with saline solution (1 mL). The lavage fluid was collected and FITC fluorescence was measured in the lavage fluid and serum using a Hitachi fluorescein fluorospectrophotometer (excitation wave: 494 nm; emission wave: 520 nm). The ratio of fluorescence between BAL and blood was calculated and expressed the pulmonary permeability index.

**Measurements of cytokines**

Interleukin-6 (IL-6) and interleukin-10 (IL-10) were quantified in serum, pancreas, lung and liver using the commercially available enzyme linked immunosorbent assay kits (R&D, Abingdon, UK). Freshly isolated tissues were homogenized in 1.5 mL phosphate buffer (20 mmol/L, pH 7.4). After centrifugation (14000 g for 5 min at 4°C), IL-6 and IL-10 concentrations were measured in the supernatant according to the manufacturer's recommendations and expressed as pg per mg proteins in tissues and pg/mL in serum. The mean concentrations of IL-6 and IL-10 mea-
Morphology
At the time of sacrifice, pancreatic tissues were rapidly removed, fixed in 4% neutral phosphate-buffered formalin, embedded in paraffin, and sectioned (5 µm). After staining with hematoxylin-eosin, sections were examined by two morphologists who were not aware of the sample identity. The extent of acinar cell necrosis was quantified by computer-assisted morphometry and expressed as a function of total acinar tissue. Acinar cell necrosis included destruction of normal pancreatic architecture in combination with inflammation. After exclusion of non-acinar cells (islets of Langerhans and perivascular and periductular adventitial tissue), the amount of acinar necrosis were morphometrically quantified using a computerized image analysis video unit (Zeiss Camera, Zeiss, Bern, Switzerland).

For pulmonary morphology, a polyvinyl catheter was inserted into the trachea and used to instill 4% neutral buffered formalin, embedded in paraffin, and sectioned (5 µm). After staining with hematoxylin-eosin, sections were examined by two morphologists who were not aware of the sample identity. The extent of acinar cell necrosis was quantified by computer-assisted morphometry and expressed as a function of total acinar tissue. Acinar cell necrosis included destruction of normal pancreatic architecture in combination with inflammation. After exclusion of non-acinar cells (islets of Langerhans and perivascular and periductular adventitial tissue), the amount of acinar necrosis were morphometrically quantified using a computerized image analysis video unit (Zeiss Camera, Zeiss, Bern, Switzerland).

MPO = myeloperoxidase. n ≥ 5 in each group. Data in CER and CONT groups were compared with Mann-Whitney test.

RESULTS
Acute pancreatitis
Cerulein administration induced severe acute pancreatitis. Serum amylase concentrations and pancreatic water content markedly increased in CER mice in comparison to CONT mice (Table 1). Pancreatic injury was also characterized by an increase in acinar cell necrosis and MPO activity.

Pre-treatment with ANS before acute pancreatitis induction significantly decreased pancreatic MPO activity (P < 0.001, Figure 1) with a concomitant decrease in

Statistical analysis
Data are median [minimum - maximum] and differences between groups were analyzed by Mann-Whitney test (comparison between CONT and CER mice) or Kruskal-Wallis and Dunn posthoc tests (comparisons between CER, CER + ANS, CER + GdCl3, and CER + ANS + GdCl3). A P value < 0.05 was considered significant.
pancreatic injury: serum amylase concentration ($P < 0.01$, Figure 2), pancreatic water content ($P < 0.01$, Figure 2), and acinar cell necrosis significantly decreased ($P < 0.01$, Figure 2). However, pre-treatment with ANS did not fully protect against pancreatic injury. Morphologic studies confirmed these findings (Figure 3).

Prevention of Kupffer cells activation by GdCl$_3$ decreased serum amylase concentration ($P < 0.05$) but did no change significantly pancreatic necrosis and pancreatic water content (Figure 2). GdCl$_3$ had no effect on pancreatic MPO activity (Figure 1). The decreased pancreatic injury was similar CER + ANS and CER + ANS + GdCl$_3$ mice.

**Acute pancreatitis-associated lung injury**

Because acute pancreatitis is frequently associated with injury in remote organs, we determined the consequences of both treatments on lung injury. CER administration increased pulmonary MPO activity and the pulmonary permeability index (Table 2). Lung injury is also evidenced by a marked thickening of the alveolar-capillary membrane (Figure 3).

Pre-treatment with ANS significantly decreased MPO activity ($P < 0.001$) and the pulmonary permeability index ($P < 0.01$) induced by CER, while GdCl$_3$ did not (Figure 4). Pulmonary injury was similarly prevented in CER + ANS and CER + ANS + GdCl$_3$ mice.

**Cytokine expression**

CER administration greatly increased IL-6 concentrations in serum but not that of IL-10 (Table 3). CER administration increased expression of both cytokines in liver, pancreas, and lungs.

GdCl$_3$ pretreatment significantly attenuated IL-6 and IL-10 concentrations in liver ($P < 0.01$ for both IL),

pancreas ($P<0.05$ and $P<0.01$ respectively), and serum ($P<0.05$ for both IL-6 and IL-10) (Figures 5 and 6). IL-6 concentrations in lungs were decreased by GdCl$_3$ ($P<0.05$) but IL-10 concentrations were not. ANS did not significantly modify IL-6 and IL-10 concentrations in liver, pancreas, and lungs. IL-6 concentrations in serum was decreased ($P<0.05$) but serum IL-10 concentrations were not modified by ANS pretreatment.

**DISCUSSION**

In mice with acute pancreatitis, neutrophil depletion reduced the severity of pancreatitis and pancreatitis-associated lung injury. Kupffer cell inactivation by GdCl$_3$ had less protective effect, although IL-6 and IL-10 concentrations in tissues were significantly decreased. The protective treatment brought by neutrophil depletion was not enhanced by inhibition of Kupffer cell activation and both treatments did not combine their protective effects.

**Neutrophil infiltration in pancreas and lungs**

Following cerulein injections in mice, neutrophil infiltration (assessed by MPO activity) was observed 12 h after the first injection. However, we previously showed that MPO activity peaks later by 24 h in pancreas and 36 h in lungs after the first injection and remains elevated by d 7 [14]. This neutrophil infiltration in tissues plays an important role in the development of acute pancreatitis and pancreatitis-associated lung injury. Thus, mice deficient in adhesion molecules such as intercellular adhesion molecule 1 (ICAM-1) or animals treated with an antineutrophil antibody [3,4] are protected from pancreatitis and remote injuries. However, the protection remained partial [3, 4]. This incomplete protection suggests that either the dose of ANS used is insufficient to completely remove all neutrophils or that additional pathways must be targeted to obtain a full protection. We previously showed that ANS injection (0.2 mL) in mice reduced the circulating neutrophils by 85% [3] while 0.5 mL/100 g in rats decreased...
the circulating neutrophils to below 200 cells/mL\textsuperscript{14}. Thus, neutrophil depletions with ANS is correct and the residual MPO activities in lungs and pancreas after ANS treatment (Figures 2 and 4) might reflect the presence of local macrophages. An incomplete protection by ANS has already been shown in mice\textsuperscript{3} or rats\textsuperscript{4} treated with cerulein. Consequently, an additional independent pathway, Kupffer cell inactivation, was targeted to further prevent acute pancreatitis.

**Role of the liver in acute pancreatitis**

The role of the liver in propagating pancreatic injury to lungs has been evidenced by inactivating Kupffer cell or diverting blood from the pancreatic vein to the systemic circulation. Thus, portocaval shunts (that dilute harmful pancreatic mediators in the systemic circulation)\textsuperscript{15,16} and inhibitors of Kupffer cell activation such as gadolinium chloride (GdCl\textsubscript{3})\textsuperscript{17} and liposome-encapsulated dichloromethylene diphosphonate (DMDP)\textsuperscript{18} significantly decrease acute pancreatitis-associated-lung injury. As expected, we showed that GdCl\textsubscript{3} pretreatment decreased IL-6 and IL-10 concentrations in the liver (Figures 5 and 6). In isolated rat livers, perfusion of pancreatic elastase activates Kupffer cells with subsequent NF-κB activation and TNF-α overproduction and this effect is abolished by GdCl\textsubscript{3} pre-treatment\textsuperscript{19}. GdCl\textsubscript{3} is specifically taken up by Kupffer cells and is not toxic by itself (when the injected dose is 100 mg/kg, iv), as previously published by Gloor et al\textsuperscript{20}. However, in our study, the pulmonary permeability index and MPO activity were not significantly decreased in comparison to CER mice (Figure 4). Pulmonary IL-6 concentrations in CER + GdCl\textsubscript{3} mice were lower than in CER mice but the IL-10 concentration decrease did not reach significance.

GdCl\textsubscript{3} pretreatment also decreased serum IL-6 and IL-10 concentration as previously published\textsuperscript{15}. In contrast to Gloor et al\textsuperscript{20} we found that GdCl\textsubscript{3} also decreased pancreatic IL-6 and IL-10 concentrations, as well as serum amylase concentration. Pancreatic necrosis, water content, and pancreatic MPO were not different between CER + GdCl\textsubscript{3} mice and CER mice, as previously described\textsuperscript{3,21}. Our results either question the specific inactivation of hepatic macrophages by GdCl\textsubscript{3} or suggest that the decreased cytokine concentrations in pancreas reflect a decreased systemic inflammatory response. In a severe form of acute pancreatitis, GdCl\textsubscript{3} pretreatment was able to reduce the mortality rate\textsuperscript{15}. The beneficial effect of GdCl\textsubscript{3} on the mortality rate remains puzzling because GdCl\textsubscript{3} administration decreases IL-10 concentrations, a cytokine which has a protective effect on the evolution of acute pancreatitis\textsuperscript{16,17}.

Kupffer cell inactivation has also been induced by other drugs such as liposome-encapsulated dichloromethylene diphosphonate which decreases apoptosis and TGF-β production in liver\textsuperscript{12} or CN1-1493 which reduced pancreatitis-associated liver injury through TNF-α and IL-1 expression\textsuperscript{18}.

In conclusion, our results confirm the role of activated neutrophils in aggravating organ injury in acute pancreatitis while the role of Kupffer cell activation is less obvious. Another more early event should probably be targeted in combination with neutrophil depletions to fully prevent the initiation of the disease.
